

## CHAPTER 2

### Tree Biomass in a Series of Pine Plantations and Fragmented Forests

#### Abstract

Biomass of tree species in a series of *Pinus kesiya* plantations and adjacent fragmented forests in Boakaew highland watershed, Chiang Mai province, were studied. The plantations included 14- to 34-year-old stands. Totally, sixty three sampling plots, 40 x 40 m<sup>2</sup> in size (three plots/age-class stand) were used. Stem diameter at 1.3 m above ground and height of all trees in each plot were measured. The tree biomass varied among plantations, 85.5 to 221.9 Mg.ha<sup>-1</sup>, separated to be 23.6-212.7 Mg.ha<sup>-1</sup> for *P. kesiya* as, and 8.1-94.1 Mg.ha<sup>-1</sup> for succession trees. The forest biomass of pine plantations was lower than fragmented forests, 117.39-253.3 Mg.ha<sup>-1</sup> (201.1 Mg.ha<sup>-1</sup> in average). The succession species had the important role on biomass stocks in plantations. The high proportion of biomass was allocated in stem component, followed by root, branch and leaf. The majority of these tree species were in the families of Fagaceae, Theaceae, Myrtaceae, Leguminosae, Euphorbiaceae, Rubiaceae and Lauraceae.

#### 2.1 Introduction

Forest clearing to agricultural land is the serious problem in highland watershed of northern Thailand. This resulted in deforestation and fragmentation. Loss of biodiversity due to the forest destruction is critical. Degrade of the watershed has been occurred caused by reducing water storage and higher surface runoff. The carbon storages in forest ecosystems have been decreased whereas the smaller amounts are accumulated in agricultural ecosystems. Moreover, the slash and burn agriculture usually leads to release organic carbon into atmospheric CO<sub>2</sub>. The CO<sub>2</sub> release into atmosphere may be higher due to reduction of ecosystem carbon storages which will further affect on increasing global warming.

Reforestation on highland watershed of Thailand is mainly planting a three needle pine species, *Pinus kesiya*. The total plantation area of about 1,500,000 ha was reported (Royal Forest Department, 1993). The plantation forest absorbs carbon dioxide and converts to organic compounds of carbohydrate which are accumulated in various plant organs. This process is very effective in reducing carbon dioxide in the atmosphere.

The plantation forests play the important role to store biomass carbon with variable amounts depending on tree species, age and growth rates, rainfall, season, site condition, etc. The carbon accumulations can be very effective in the young stand and will be reduced in the older stand (Ciesla, 1995).

The reforestation had been conducted at the Boakaew Watershed Management Station, Chiang Mai province, during 1975-1995 with the total area of 2,285 ha. A pine, *Pinus kesiya*, was planted in pure stands because this pine is a pioneer species which tolerates to harsh sites, poor soil and grass competition (Harcharik and Kunkle, 1978). It has good survival and fast growth rate (Bandaratillake, 1989). The aims of this research are to assess biomass accumulations of pine trees and succession tree

species grown in a series of pine plantations, and adjacent fragmented montane forests. The data are useful information for improving plantation techniques of reforestation.

## 2.2 Study Area

The research area was located in the Boakaew Watershed Management Station, ( $18^{\circ}45' - 21^{\circ}00' \text{N}$ ,  $98^{\circ}25' - 98^{\circ}40' \text{E}$ ), Chiang Mai province, Thailand, about 82 km north of Chiang Mai province. The altitude of research site ranges from 1,200 to 1,600 m above mean sea level (Figure 2-1). The climate is cool throughout a year. Mean monthly temperature is  $20.9^{\circ}\text{C}$ , with a maximum of  $25.4^{\circ}\text{C}$  in April and minimum of  $16.4^{\circ}\text{C}$  in December. Average annual rainfall is 1,894 mm. The forest type is pine-lower montane forest.

The local people utilize the natural forest, either wood or non-wood products. Some tree species were cut for house construction, and some pine trees were fallen for collecting cones, and sold to merchant. Many oaks were cut for making fire wood.

The main causes of deforestation in Boakaew Watershed Management Station were forest clearing for agriculture and shifting cultivation. Forest rehabilitation in this area used the native pioneer fast growing species including *Pinus kesiya*, *Prunus cerasoides*, *Docynia indica* and *Betula alnoides* planted in pure stands to recover the degraded watershed land during 1975-1995 with the area of 2,285 ha (Table 2-1). After 1995, the mixed plantation of local species was used.

**Table 2-1** Plantation areas of Boakaew Watershed Management Station

## 2.3 Materials and Methods

### 2.3.1 Vegetation Sampling

Twenty-one age class pine plantations including 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33 and 34 years old were chosen. Three sampling plots (replications),  $40 \times 40 \text{ m}^2$  in size, were arranged in each age-class plantation. Totally, sixty three plots were used for growth and wood production studies of pine plantations. In each plot, stem girth at breast height (gbh) and tree height of pine and other trees were measured for calculating the forest biomass.

### 2.3.2 Physical Data of Sampling Plots

All plots were recorded for positions using GPS (Global Positioning System) at the center of plot, altitude, slope aspect and gradient. The slope gradient was measured every ten meters along the plot using an abney.

### 2.3.3 Tree Biomass of *Pinus kesiya* Plantations

The data of stem girth at breast height (gbh) and tree height of pine trees in a series of plantations were used for biomass calculation. Four sample pine trees were cut from four age-class plantations from the young to old plantations; 20, 26, 30 and 33 years old. The fallen trees were measured for biomass according to a stratified-clip technique. Finally, the collected data were used to adjust the allometric equation. (Sahunalu, 1995)

$$W = A(D^2H)^h$$

Where,  
 $W$  = biomass of stem, branch, leaf or root (dry weight per area)  
 $D$  = diameter (cm)  
 $H$  = tree height (m)  
 $A, h$  = constant

### 2.3.4 Forest Biomass of Fragmented Forests

Biomass accumulations in adjacent fragmented forests and other succession broad-leaved trees in pine plantations are calculated using allometric equations of Tsutsumi *et al.* (1983);

$W_S$ (stem)	=	$0.0509 (D^2H)^{0.919}$	$R^2 = 0.978$
$W_B$ (branch)	=	$0.00893 (D^2H)^{0.977}$	$R^2 = 0.890$
$W_L$ (leaf)	=	$0.0140 (D^2H)^{0.669}$	$R^2 = 0.714$
$W_R$ (root)	=	$0.0313 (D^2H)^{0.805}$	$R^2 = 0.981$

Where,  
 $W$  = biomass (kg)  
 $D$  = diameter (cm)  
 $H$  = height (m)

## 2.4 Results

### 2.4.1 Biomass of Pine Trees in a Series of Pine Plantations

#### (1) Pine Growths

The growths of pine trees in 21 age-class pine plantations of 14 to 34 years old at Boakaew Watershed Management Station were analyzed in mean and increment values of stem diameter at breast height (dbh) and tree height for each age-class stand (Table 2-2). The height and stem diameter growths were varied among different age plantations. However, they did not increase continuously with stand ages. The height and dbh of pine trees in some older stands were lower than the younger stands. Some plantations covered the good site with more fertile soil and higher moisture. In contrast, some grew on the steep upper/ridge slope which had shallow soil and dry site. Different densities of pine trees and succession tree species are another important factor affecting pine growths.

The mean height (H) and dbh of these stands were in ranges of 15.31-23.30 m and 24.24-35.37 cm, respectively. The annual height increment varied between 0.52-1.15 m with the mean of 0.81 m/yr, whereas the annual dbh increment was 0.94-2.24 cm, and 1.28 cm/yr of mean value.

**Table 2-2** Pine growths in a series of pine plantations with different stand ages

Ages (yrs)	Growths		Annual growth increment	
	H (m)	DBH (cm)	H (m/yr)	DBH (cm/yr)
14	16.13	31.35	1.15	2.24
15	15.31	28.69	1.02	1.91
16	17.59	27.61	1.10	1.73
17	15.87	26.44	0.93	1.56
18	17.14	29.33	0.95	1.63
19	17.32	26.08	0.91	1.37
20	17.07	27.03	0.85	1.35
21	19.01	26.98	0.91	1.28
22	17.11	25.72	0.78	1.17
23	18.41	25.70	0.80	1.12
24	18.23	24.24	0.76	1.01
25	18.47	25.25	0.74	1.01
26	19.72	29.81	0.76	1.15
27	20.26	26.46	0.75	0.98
28	18.68	33.44	0.67	1.19
29	15.13	28.53	0.52	0.98
30	19.58	32.79	0.65	1.09
31	21.49	35.37	0.69	1.14
32	20.46	32.32	0.64	1.01
33	23.30	34.52	0.71	1.05
34	21.47	32.10	0.63	0.94
Average			0.81	1.28

**Figure 2-2** Over views of pine plantations at Boakaew Watershed Management Station

## (2) Biomass of Pine Trees

Above-ground biomass of pine trees was calculated from allometric equations which were obtained by using four felling trees from different age-class plantations as following equations. The root biomass of pine trees was based on allometric equations of Tsutsumi *et al.* (1983).

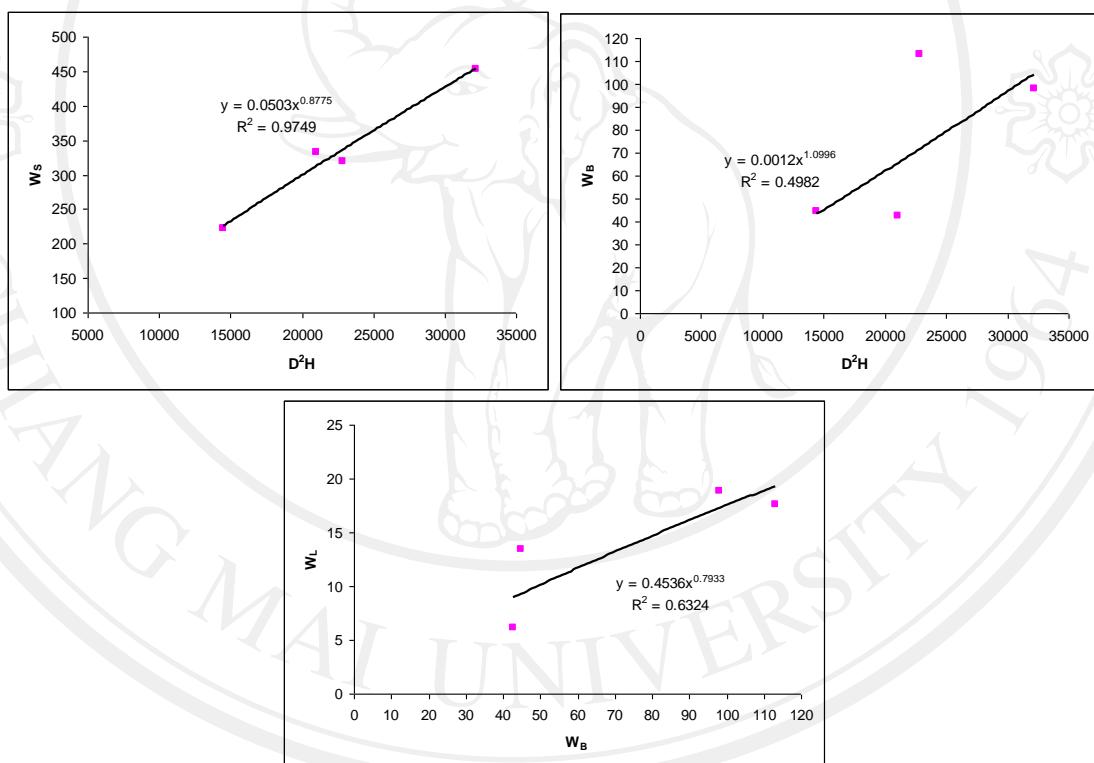

$$\begin{aligned} W_S &= 0.0503 (D^2H)^{0.8775} & R^2 &= 0.9749 \\ W_B &= 0.0012 (D^2H)^{1.0996} & R^2 &= 0.4982 \\ W_L &= 0.4536 (W_B)^{0.7933} & R^2 &= 0.6324 \end{aligned}$$

Where,

$W$  = biomass (kg)

$D$  = diameter (cm)

$H$  = height (m)

**Figure 2-3** Allometric equations of a above-ground biomass of pine

Similar to pine growths, the pine biomass in different age plantations did not increase continuously with stand ages. The values were 23.6 to 212.7 Mg.ha<sup>-1</sup>. The lowest amount was found in the 15-year-old stand, whereas the largest amount was occurred in the 33-year-old stand. The majority of pine biomass was allocated in the stem component, followed by root, branch and leaf (Table 2-3). The high fluctuation of pine biomass was observed among the pine plantations caused by many factors such as spacing of planting, tree densities, competition with succession trees, site conditions, etc.

**Table 2-3** Biomass of pine trees in a series of pine plantations

Age (year)	Tree biomass ( $\text{Mg.ha}^{-1}$ )				
	Stem	Branch	Leaf	Root	Total
14	37.9	8.1	1.6	11.9	59.5
15	15.1	3.1	0.6	4.8	23.6
16	79.2	16.8	3.3	25.0	124.2
17	15.5	3.0	0.6	5.0	24.2
18	59.0	12.2	2.4	18.7	92.4
19	74.5	14.7	3.1	24.0	116.3
20	83.5	16.6	3.5	26.9	130.5
21	86.3	17.6	3.6	27.6	135.1
22	56.9	11.1	2.4	18.5	88.8
23	44.7	8.9	1.9	14.5	70.0
24	55.1	10.6	2.3	18.0	86.0
25	71.8	14.0	3.0	23.3	112.2
26	115.5	25.5	4.8	36.0	181.8
27	70.8	15.0	2.9	22.3	111.0
28	80.7	18.7	3.3	24.7	127.4
29	45.1	9.1	1.9	14.5	70.5
30	79.9	18.2	3.3	24.6	126.0
31	46.2	10.8	1.9	14.1	73.0
32	90.7	20.2	3.7	28.1	142.7
33	134.4	31.8	5.5	40.9	212.7
34	61.7	14.0	2.5	19.1	97.3

#### 2.4.2 Biomass of Succession Tree Species in a Series of Pine Plantations

The number of succession tree species in different age pine plantations was different, varying 16-69 species. The biomass amounts of these trees were calculated using the allometric equations of Tsutsumi *et al.* (1983).

The results showed that the biomass in these pine plantations were different from 8.1 to 94.1  $\text{Mg.ha}^{-1}$ . Their biomass did not increase with plantation ages. It was the lowest in 20-year-old stand, 8.1  $\text{Mg.ha}^{-1}$ , and the highest amount was occurred in 31-year-old stand, 94.1  $\text{Mg.ha}^{-1}$ . The larger biomass of succession trees was due to existing bigger trees with high density. These succession tree species played the important role on plantation biomass stocks. The majority of their biomass was allocated in stem component, followed by root, branch and leaf (Table 2-4).

#### (3) Total Forest Biomass in a Series of Plantations

The total forest biomass in a series of 21 age-class pine plantations involved biomass of pine and succession broad-leaved trees. The amounts were varied between 70.5-248.2  $\text{Mg.ha}^{-1}$  (Table 2-5 and Figure 2-4). They did not increase with stand ages. It was the lowest in 15-year-old stand, and the highest amount was observed in 26-year-old stand. The low amounts were found in plantations with altitude above 500 m msl., and those in areas between 1,314-1,453 m msl. had the high total biomass. The majority of total biomass was allocated in stem component, followed by root, branch and leaf (Table 2-6).

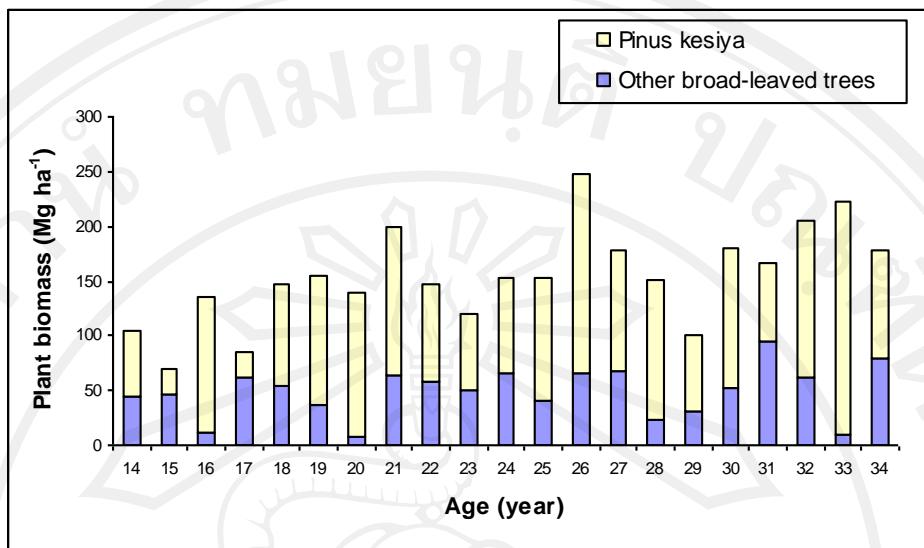

The contribution of succession trees to total biomass can be considered from the percentage distribution. The percentages of succession tree biomass were different among pine plantations. It was the highest in 17-year-old stand, and the lowest in 33-

**Table 2-4** Biomass of succession trees in a series of pine plantations

Age (yrs)	Plant biomass ( $Mg.ha^{-1}$ )				
	Stem	Branch	Leaf	Root	Total
14	28.8	5.0	1.2	9.8	44.8

**Figure 2-4** Total forest biomass in a series of pine plantations

year-old stand. The biomass of succession trees was 71.7% in the 17-year-old stand which had the highest total biomass while the 33-year-old stand, the lowest total forest biomass ecosystem, had the value of 4.2%.

In 14-year-old stand, among 35 species of succession trees, *Glochidion sphaerogynum* (16.11%) had the highest biomass, followed by *Schima wallichii* (8.72%), *Albizia chinensis* (5.67%), *Callicarpa arborea* (2.75%), *Litsea* sp. (2.51%), *Castanopsis diversifolia* (2.33%), *Ficus ribes* (1.92%), *Eriolaena candollei* (1.71%), etc.

In 15-year-old stand, there was 53 species of succession trees. *S. wallichii* (13.65%) had the highest biomass. The trees having the lower biomass were *C. acuminatissima* (11.45%), *Engelhardtia spicata* (6.75%), *Beilschmiedia gammieana* (6.73%), *Dillenia aurea* (5.19%), *Ternstroemia gymnanthera* (5.05%), *Helicia terminalis* (3.68%), *Phoebe paniculata* (3.11%), *Trichilla connaroides* (2.88%), etc.

In 16-year-old stand, 32 species of succession trees were existed. *S. wallichii* (3.51%) had the highest biomass, followed by *Canarium subulatum* (1.30%), *Wendlandia tinctoria* (1.25%), *Spatholobus parviflorus* (1.12%), etc.

In 17-year-old stand, the high number as 60 species of succession trees was found. *S. wallichii* (10.63%) had the highest biomass, followed by *Myrica esculenta* (8.81%), *E. spicata* (7.44%), *C. diversifolia* (7.03%), *Quercus semiserrata* (6.79%), *H. terminalis* (5.82%), *C. acuminatissima* (4.43%), *Phoebe cathia* (3.97%), *W. tinctoria* (3.71%), *Syzygium albiflorum* (3.20%), *Elaeocarpus sphaericus* (2.75%), etc.

In 18-year-old stand, among 45 species of succession trees, *C. purpurea* (7.35%) had the highest biomass, followed by *S. wallichii* (3.58%), *E. candollei* (3.45%), *C. acuminatissima* (3.24%), *Quercus vestita* (3.14%), *C. dievrsifolia* (3.00%), *W. tinctoria* (2.82%), *G. sphaerogynum* (2.67%), *Dalbergia assamica* (2.10%), *Acacia megaladema* (1.84%), etc.

In 19-year-old stand, existing succession trees were 37 species. *C. diversifolia* (6.50%) had the highest biomass, followed by *E. candollei* (4.39%), *C. purpurea*

(4.35%), *Albizia chinensis* (2.88%), *W. tinctoria* (2.53%), *T. gymnanthera* (1.61%), etc.

In 20-year-old stand, the number succession tree species the lowest among plantations as 16 species. *Bauhinia variegata* (3.33%) had the highest biomass, followed by *E. candollei* (2.86%), *S. albiflorum* (0.69%), *C. diversifolia* (0.48%), etc.

In 21-year-old stand, there was 40 species of succession trees. *S. wallichii* (11.22%) had the highest biomass, followed by *C. acuminatissima* (4.87%), *Anneslea fragrans* (4.75%), *S. albiflorum* (3.52%), *C. diversifolia* (3.10%), *Lithocarpus elegans* (2.54%), *W. tinctoria* (2.00%), *E. sphaericus* (1.84%), *M. esculenta* (1.05%), *Buchanania lanzae* (1.02%), etc.

In 22-year-old stand, the high number as 60 species of succession trees was found. *Q. brandisiana* (9.53%) had the highest biomass, followed by *Q. vestita* (4.67%), *L. polystachyus* (4.06%), *Dalbergia cultrata* (3.03%), *S. wallichii* (2.82%), *W. tinctoria* (2.47%), *Gluta obovata* (2.20%), *L. elegans* (2.13%), *Tristania rufescens* (1.69%), *L. sootepensis* (1.65%), *C. purpurea* (1.59%), *F. ribes* (1.28%), *A. fragrans* (1.22%), etc.

In 23-year-old stand, the succession tree species in this stand were 49 species. *Q. vestita* (16.79%) had the highest biomass, followed by *L. polystachyus* (10.89%), *S. wallichii* (4.00%), *L. sootepensis* (2.45%), *L. elegans* (1.81%), *Q. kingiana* (1.71%), etc.

In 24-year-old stand, existing succession tree species were 45 species. *C. diversifolia* (22.49%) had the highest biomass, followed by *S. wallichii* (7.61%), *E. sphaericus* (5.45%), *Sacrospermum arboreum* (3.71%), *S. cumini* (3.65%), *H. terminalis* (2.03%), *Erythrina subumbra* (1.66%), etc.

In 25-year-old stand, succession tree species in this stand consisted of 38 species. *S. wallichii* (8.74%) had the highest biomass, followed by *C. diversifolia* (5.00%), *S. albiflorum* (4.66%), *C. purpurea* (3.17%), *A. fragrans* (2.42%), *C. acuminatissima* (2.16%), *W. tinctoria* (1.36%), etc.

In 26-year-old stand, it was 30 species of succession tree species existed in this plantation. *S. wallichii* (11.86%) had the highest biomass, followed by *Q. semiserrata* (4.65%), *C. diversifolia* (4.59%), *H. nilagirica* (2.98%), *S. albiflorum* (1.76%), *T. gymnanthera* (1.64%), *Stereospermum neuranthum* (1.57%), *S. cumini* (1.12%), *C. purpurea* (0.94%), *D. aurea* (0.82%), *P. paniculata* (0.78%), etc.

In 27-year-old stand, the number of succession tree species was high as 69 species. *S. wallichii* (25.30%) had also the highest biomass. The lower amounts were found for *C. diversifolia* (2.66%), *G. sphaerogynum* (2.53%), *P. paniculata* (2.38%), *Elaeocarpus sphaericus* (2.18%), *D. velutina* (1.76%), *Betula alnoides* (1.63%), *B. lanzae* (1.51%), *C. purpurea* (1.40%), *W. tinctoria* (1.07%), etc.

In 28-year-old stand, 34 species of succession tree species was composed in this stand. The tree species having the highest biomass was *S. wallichii* (13.93%). They were followed by *E. spicata* (1.66%), *G. sphaerogynum* (1.48%), *Markhamia stipulata* (0.82%), *C. diversifolia* (0.79%), etc.

In 29-year-old stand, among 31 species of succession tree species, *C. purpurea* (10.01%) had the highest biomass. The lower amounts were calculated for *S. wallichii* (8.46%), *H. terminalis* (5.98%), *A. fragrans* (3.67%), etc.

In 30-year-old stand, the total number of succession tree species was 35 species. *C. diversifolia* (12.15%) had the highest amount of biomass, followed by *S.*

*wallichii* (11.57%), *C. purpurea* (3.77%), *D. assamica* (2.92%), *E. spicata* (2.59%), *L. elegans* (2.15%), etc.

In 31-year-old stand, there was 38 succession tree species, and *C. diversifolia* (21.13%) had the highest amount of biomass. They were followed by *S. wallichii* (16.43%), *C. Acuminatissima* (7.09%), *S. Albiflorum* (4.14%), *W. tinctoria* (3.86%), *M. esculenta* (1.68%), *Olea salicifolia* (1.63%), *S. cumini* (1.63%), *H. terminalis* (1.56%), etc.

In 32-year-old stand, the total succession tree species in this stand was 33 species. *S. wallichii* (17.43%) had the highest biomass, and followed by *S. cumini* (6.58%), *C. acuminatissima* (4.93%), *P. paniculata* (1.95%), *Xanthophyllum virens* (1.44%), *E. sphaericus* (1.16%), *Magnolia henryi* (1.12%), *C. tribuloides* (0.91%), etc.

In 33-year-old stand, 52 species of succession tree species was existed. Wild banana, *M. acuminata* (1.80%), had the highest biomass, followed by *W. tinctoria* (1.36%), *Cimnamomum iners* (1.01%), *A. chinensis* (0.58%), etc.

In the oldest stand of 34 years old, *C. purpurea* (23.01%) had the highest biomass among succession trees of 49 species. The lower amounts were found for *Q. vestita* (10.39%), *S. wallichii* (7.47%), *Q. brandisiana* (5.09%), *S. cumini* (2.45%), *W. tinctoria* (1.30%), *D. assamica* (1.19%), etc.

**Table 2-6** Biomass of tree species in a series of pine plantations

### 2.4.3 Biomass of Fragmented Forests

Biomass of tree species in fifteen fragmented forests were different, 117.3 to 253.3 Mg.ha<sup>-1</sup> (201.1 Mg.ha<sup>-1</sup> in average). It was the lowest in FF10, and the highest in FF1. The average amounts allocated in stem, branch, leaf and root components were 130.0, 40.5, 3.3 and 27.3 Mg.ha<sup>-1</sup>, respectively (Table 2-7 and Figure 2-5). The majority of biomass was stored in tree species of Fagaceae, Pinaceae and Theaceae families (Table 2-8).

Among 103 species in fifteen fragmented forests, *Pinus kesiya* had the highest amount of biomass. The trees having the lower amounts were *C. acuminatissima*, *S. wallichii*, *C. diversifolia*, *Q. brandisiana*, *T. rufescens*, etc.

**Table 2-7** Tree biomass in fragmented forests

Fragmented forest	Tree biomass (Mg.ha <sup>-1</sup> )				
	Stem	Branch	Leaf	Root	Total
FF1	164.2	51.7	3.9	33.5	253.3
FF2	109.2	32.5	3.4	25.0	170.0
FF3	154.1	46.9	4.3	33.7	239.0
FF4	148.5	47.4	3.3	29.5	228.7
FF5	132.3	40.9	3.5	28.2	204.8
FF6	128.6	41.3	2.8	25.3	198.0
FF7	106.0	32.9	2.8	22.4	164.1
FF8	115.5	36.4	2.8	23.7	178.4
FF9	124.6	39.6	3.0	25.3	192.4
FF10	75.6	23.3	2.1	16.3	117.3
FF11	132.6	39.7	3.9	30.0	206.3
FF12	156.4	48.3	4.1	33.3	242.1
FF13	153.7	49.3	3.5	30.5	236.9
FF14	127.4	39.0	3.4	27.5	197.4
FF15	121.4	37.7	3.0	25.4	187.5
Average	130.0	40.5	3.3	27.3	201.1

**Figure 2-6** Over views of fragmented forests at Boakaew Watershed Management Station

## 2.5 Discussion

The total biomass of tree species in a series of pine plantations included those of pine trees and succession tree species. There were no plantations of 1 to 13 years old in this watershed management station since the pine plantation project was terminated in 1995. Thereafter, tree planting is changed to re-enriched planting technique in deteriorated forest. For pine trees, the pine biomass in 14- to 34-year-old plantations did not increased with stand ages. The data are different from Miller (1989) who reports that biomass in stem, branch and foliages of *Pinus nigra* was increased with stand ages during 20 years after planting. Many factors including densities of pine and succession trees, site factors and forest fire influenced on pine growths in this study. These factors affected their growths and biomass allocation.

The densities of pine trees in different age plantations were different. At the beginning of planting, the planting space of tree species was  $4 \times 4 \text{ m}^2$ . However, mixed plantation was taken in 28- to 32-year-old stands by planting pine with *Docynia indica*. The mixed plantation of pine with *Prunus cerasoides* was done in 18-year-old stand. For 17-year-old stand, it was the mixture of pine, *Docynia indica* and *Prunus cerasoides*. More tree species were planted in the younger stands: 16-year-old stand; pine, *Docynia indica*, *Prunus cerasoides*, *Betula alnoides* and *Ternstroemia symnanthera*, 15-year-old stand; pine, *Docynia indica*, *Prunus cerasoides*, *Betula alnoides* and *Mangifera* sp., and 14-year-old stand; pine, *Docynia indica*, *Prunus cerasoides*, *Betula alnoides*, *Mangifera* sp. and *Diospyros* sp. The pine densities were thus lower in mixed plantations. The limit growing space in the forest is an important factor affecting tree size and growth (Bowen and Nambiar, 1989; Oliver and Larson, 1996). Standing dead pine trees were occurred in some plantations, and further affected on the density.

The site factor particularly soil fertility affects on tree growths in the plantation forest (Bowen and Nambiar, 1984). The other factors such as moisture and forest fire are also important (Fisher and Binkley, 2000). As will be described in Chapter 4, the soil fertility indicated by amounts of organic matter and available nutrients was not increased with plantation ages but had the high variations according site conditions.

The succession tree species have influenced on pine trees in plantations. In the young plantations, the succession trees may grow beneath pine canopy wheras in the older plantations the heights may be nearly the same or over the pine canopy. The litterfall of succession broad-leaved trees has influenced on soil properties such as acidity and releasing nutrients. In the mixed plantations, competition among tree species limit the stand development and tree growths (Oliver and Larson, 1996)

The highest amount of pine biomass in plantations was found in 33-year-old stand,  $212.7 \text{ Mg.ha}^{-1}$ . It was lower than the most abundant fragmented forest in the watershed (FF12) ( $242.1 \text{ Mg.ha}^{-1}$ ). In the 33-year-old stand, the biomass contribution of succession trees was  $9.2 \text{ Mg.ha}^{-1}$ , and resulted in total stand biomass of  $221.9 \text{ Mg.ha}^{-1}$ . Their highest biomass contribution was observed in 31-year-old stand,  $94.1 \text{ Mg.ha}^{-1}$ . Therefore, the succession tree species had the important role on biomass stocks in pine plantations. These tree species were in the families of Fagaceae, Theaceae, Myrtaceae, Leguminosae, Euphorbiaceae, Rubiaceae and Lauraceae.
